CNN

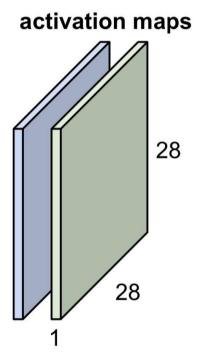

Deep Learning - Spring 2020

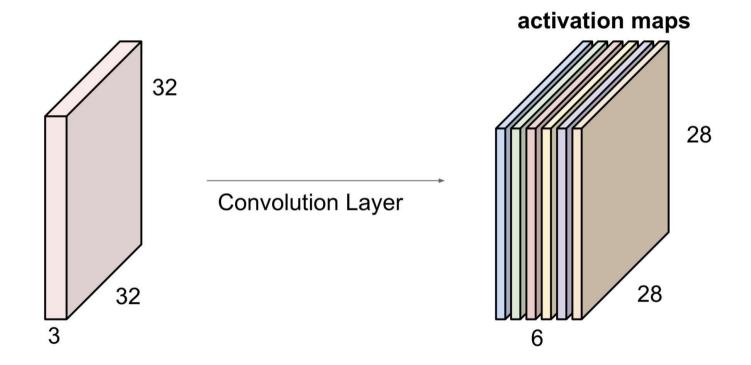

- N: Input size (height & width), F:Filter size, S: Stride, P: Padding size
- Output size: O = (N + 2 * P F) / S + 1
- K: number of filters
- Depth = K = Number of output channels (C_out)
- Transforms (N * N * C_in) into (O * O * C_out)
- K biases
- # of parameters: F * F * C in * K + K
- Common settings: K = powers of 2 (32, 64, 128,)
- [F=3, S=1, P=1], [F=5, S=1, P=2], [F=1, S=1, P=0]
- Pooling (Common settings: [F=2, S=2], [F=3, S=2])

Conv2d

CLASS torch.nn.Conv2d(in_channels, out_channels, kernel_size, stride=1, padding=0, dilation=1, groups=1, bias=True, padding_mode='zeros')

Applies a 2D convolution over an input signal composed of several input planes.

In the simplest case, the output value of the layer with input size $(N, C_{\rm in}, H, W)$ and output $(N, C_{\rm out}, H_{\rm out}, W_{\rm out})$ can be precisely described as:

$$\operatorname{out}(N_i, C_{\operatorname{out}_j}) = \operatorname{bias}(C_{\operatorname{out}_j}) + \sum_{k=0}^{C_{\operatorname{in}}-1} \operatorname{weight}(C_{\operatorname{out}_j}, k) \star \operatorname{input}(N_i, k)$$

where \star is the valid 2D cross-correlation operator, N is a batch size, C denotes a number of channels, H is a height of input planes in pixels, and W is width in pixels.

Ex.

```
>>> layer = Conv2d(in_channels=64, out_channels=128, kernel_size=3)
>>> layer.weight.shape
torch.Size([128, 64, 3, 3])
>>> layer.bias.shape
torch.Size([128])
```

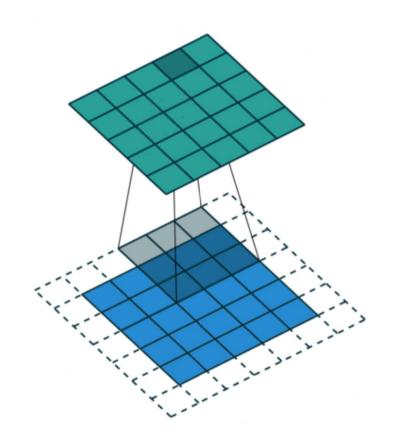

Types of Convolution

Types of Convolution

- Dilated Convolutions
- Transposed Convolutions
- Separable Convolutions

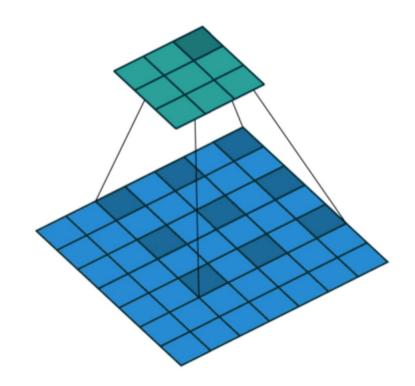

Example:

- Kernel Size = 3
- Stride = 1
- Padding = 1

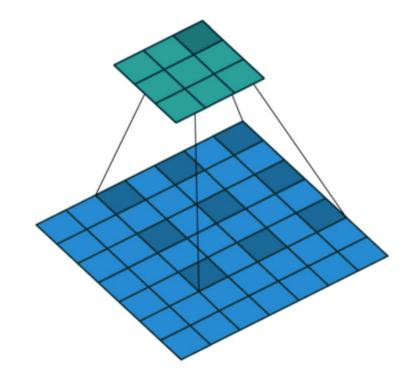

Dilated Convolutions

- Dilated convolutions introduce another parameter to convolutional layers called the dilation rate.
- This defines a spacing between the values in a kernel.
- Ex: A 3x3 kernel with a dilation rate of 2 will have the same field of view as a 5x5 kernel, while only using 9 parameters.

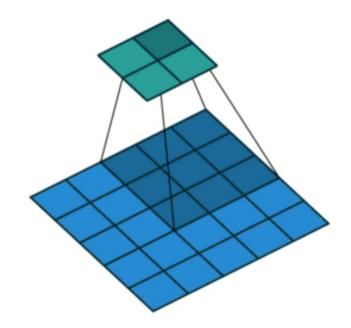

Dilated Convolutions (cont.)

- This delivers a wider field of view at the same computational cost.
- Dilated convolutions are particularly popular in the field of real-time segmentation.
- Use them if you need a wide field of view and cannot afford multiple convolutions or larger kernels.

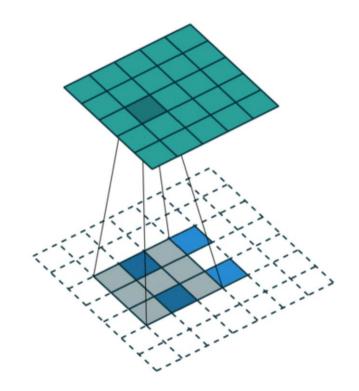

Transposed Convolutions

- a.k.a. deconvolutions or fractionally strided convolutions
- Some sources use the name deconvolution, which is inappropriate. An actual deconvolution reverts the process of a convolution. (mathematically inverse process)

Transposed Convolutions (cont).

- This way we can combine the upscaling of an image with a convolution, instead of doing two separate processes.
- This may not be the mathematical inverse, but for Encoder-Decoder architectures, it's still very helpful.
- It merely reconstructs the spatial resolution from before and performs a convolution.

Separable Convolutions

- In a separable convolution, we can split the kernel operation into multiple steps.
- Let's express a convolution as y = conv(x, k) where y is the output image, x is the input image, and k is the kernel. Easy. Next, let's assume k can be calculated by: k = k1.dot(k2). This would make it a separable convolution because instead of doing a 2D convolution with k, we could get to the same result by doing 2 1D convolutions with k1 and k2.

y filter

Custom DataLoader

Custom Dataset

- A lot of effort in solving any machine learning problem goes in to preparing the data.
- PyTorch provides many tools to make data loading easy and hopefully, to make your code more readable.

```
import torch
class Dataset(torch.utils.data.Dataset):
  'Characterizes a dataset for PyTorch'
  def init (self, list IDs, labels):
        'Initialization'
        self.labels = labels
        self.list IDs = list IDs
  def len (self):
        'Denotes the total number of samples'
        return len(self.list IDs)
  def getitem (self, index):
        'Generates one sample of data'
       # Select sample
       ID = self.list IDs[index]
       # Load data and get label
        X = torch.load('data/' + ID + '.pt')
       y = self.labels[ID]
        return X, y
```

Dataset class

- A lot of effort in solving any machine learning problem goes in to preparing the data.
- torch.utils.data.Dataset is an abstract class representing a dataset.
- Your custom dataset should inherit Dataset and override the following methods:
 - __len__ so that len(dataset) returns the size of the dataset.
 - <u>getitem</u> to support the indexing such that dataset[i] can be used to get ith sample
 - We will read the csv in __init__ but leave the reading of images to __getitem__
 - This is memory efficient because all the images are not stored in the memory at once but read as required.
 - Our dataset will take an optional argument transform so that any required processing can be applied on the sample.

Loading data

Parameters

```
params = {'batch size': 64,
          'shuffle': True,
          'num workers': 6}
max epochs = 100
# Datasets
partition = # IDs
labels = # Labels
# Generators
training set = Dataset(partition['train'], labels)
training generator = torch.utils.data.DataLoader(training set, **params)
validation set = Dataset(partition['validation'], labels)
validation generator = torch.utils.data.DataLoader(validation set, **params)
# Loop over epochs
for epoch in range(max epochs):
    # Training
    for local batch, local labels in training generator:
        # Transfer to GPU
        local batch, local labels = local batch.to(device), local labels.to(device)
        # Model computations
        [\ldots]
```

Augmentation

Transformers, Data

Why Transforms?

- One issue with most image data is that the samples are not of the same size.
- Moreover, we may need to crop or resize our images according to our application
- Most neural networks expect the images of a fixed size.
- Therefore, we will need to write some prepocessing code.
- You can write your own custom transforms or use TorchVision predefined transforms.

- Rescale: to scale the image
- RandomCrop: to crop from image randomly. This is data augmentation.
- ToTensor: to convert the numpy images to torch images (we need to swap axes).

TorchVision

- You might not even have to write custom classes.
- torchvision package provides some common datasets and transforms.
- E.g. One of the more generic datasets available in torchvision is ImageFolder.
- It assumes that images are organized in the following way:

```
root/ants/xxx.png
root/ants/xxy.jpeg
root/ants/xxz.png
.
.
.
root/bees/123.jpg
root/bees/nsdf3.png
root/bees/asd932_.png
```

```
import torch
from torchvision import transforms, datasets
data transform = transforms.Compose([
        transforms.RandomSizedCrop(224),
        transforms.RandomHorizontalFlip(),
        transforms.ToTensor(),
        transforms.Normalize(mean=[0.485, 0.456, 0.406],
                             std=[0.229, 0.224, 0.225])
    1)
hymenoptera_dataset = datasets.ImageFolder(root='hymenoptera_data/train',
                                           transform=data transform)
dataset loader = torch.utils.data.DataLoader(hymenoptera dataset,
                                              batch size=4, shuffle=True,
                                             num_workers=4)
```

Normalization

Why Normalization?

- It normalizes each feature so that they maintains the contribution of every feature, as some feature has higher numerical value than others. This way our network can be unbiased (to higher value features).
- It makes the Optimization faster because normalization doesn't allow weights to explode all over the place and restricts them to a certain range.
- An unintended benefit of Normalization is that it helps network in Regularization
- Batch Norm makes loss surface smoother
- It reduces **Internal Covariate Shift**. It is the change in the distribution of network activations due to the change in network parameters during training. To improve the training, we seek to reduce the internal covariate shift.

Batch Normalization

 <u>Batch normalization</u> is a method that normalizes activations in a network across the mini-batch of <u>definite size</u>. For each feature, batch normalization computes the mean and variance of that feature in the mini-batch. It then subtracts the mean and divides the feature by its mini-batch standard deviation.

$$\mu_{\mathcal{B}} \leftarrow \frac{1}{m} \sum_{i=1}^{m} x_i$$
 // mini-batch mean
$$\sigma_{\mathcal{B}}^2 \leftarrow \frac{1}{m} \sum_{i=1}^{m} (x_i - \mu_{\mathcal{B}})^2$$
 // mini-batch variance

Batch Norm (cont.)

```
Input: Values of x over a mini-batch: \mathcal{B} = \{x_{1...m}\};
                              Parameters to be learned: \gamma, \beta
 Output: \{y_i = BN_{\gamma,\beta}(x_i)\}
\mu_{\mathcal{B}} \leftarrow \frac{1}{m} \sum_{i=1}^{m} x_{i} \qquad // \text{ mini-batch mean}
\sigma_{\mathcal{B}}^{2} \leftarrow \frac{1}{m} \sum_{i=1}^{m} (x_{i} - \mu_{\mathcal{B}})^{2} \qquad // \text{ mini-batch variance}
\widehat{x}_{i} \leftarrow \frac{x_{i} - \mu_{\mathcal{B}}}{\sqrt{\sigma_{\mathcal{B}}^{2} + \epsilon}} \qquad // \text{ normalize}
y_{i} \leftarrow \gamma \widehat{x}_{i} + \beta \equiv \text{BN}_{\gamma,\beta}(x_{i}) \qquad // \text{ scale and shift}
```

Weight Normalization

- Weight Normalization normalize weights of a layer instead of normalizing the activations directly.
- It reparameterizes the weights w as:

$$oldsymbol{w} = rac{g}{\|oldsymbol{v}\|} oldsymbol{v}$$

Layer Normalization

- <u>Layer normalization</u> normalizes input across the features instead of normalizing input features across the batch dimension in batch normalization.
- performs better than batch norm in case of RNNs

$$\mu_{i} = \frac{1}{m} \sum_{j=1}^{m} x_{ij} \sigma_{i}^{2} = \frac{1}{m} \sum_{j=1}^{m} (x_{ij} - \mu_{i})^{2} \hat{x_{ij}} = \frac{x_{ij} - \mu_{i}}{\sqrt{\sigma_{i}^{2} + \epsilon}}$$

Switchable Normalization

- This paper proposed switchable normalization, a method that uses a weighted average of different mean and variance statistics from batch normalization, instance normalization, and layer normalization.
- The authors showed that switch normalization could potentially outperform batch normalization on tasks such as image classification and object detection.
- The paper showed that the instance normalization were used more often in earlier layers, batch normalization was preferred in the middle and layer normalization being used in the last more often. Smaller batch sizes lead to a preference towards layer normalization and instance normalization.

Transfer Learning

Transfer learning

- Using a network pretrained on a large dataset (e.g. ImageNet)
- Fine-tune the pre-trained network on our own dataset
- If the new dataset is very small, it's better to train only the final layers of the network to avoid overfitting
- Add new layers and retrain them only
- The earlier features of a ConvNet contain more generic features (e.g. edge detectors or color blob detectors), but later layers of the ConvNet becomes progressively more specific to the details of the classes contained in the original dataset

Transfer learning

Implementation

```
model conv = torchvision.models.resnet18(pretrained=True)
for param in model conv.parameters():
    param.requires grad = False
# Parameters of newly constructed modules have requires grad=True by default
num_ftrs = model_conv.fc.in features
model conv.fc = nn.Linear(num ftrs, 2)
model conv = model conv.to(device)
criterion = nn.CrossEntropyLoss()
# Observe that only parameters of final layer are being optimized as
# opposed to before.
optimizer conv = optim.SGD(model conv.fc.parameters(), lr=0.001, momentum=0.9)
# Decay LR by a factor of 0.1 every 7 epochs
exp_lr_scheduler = lr_scheduler.StepLR(optimizer_conv, step_size=7, gamma=0.1)
```

CNN Architectures

ImageNet

- Near 15 million images containing more than 20,000 categories
- Labeled by Amazon Mechanical Turk
- ImageNet Large Scale Visual Recognition Challenge (ILSVRC)

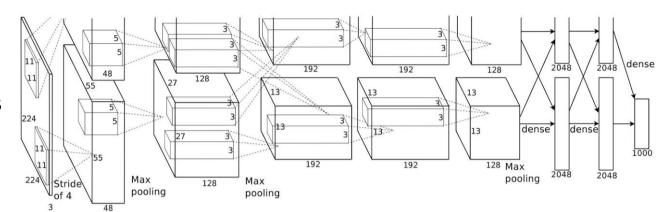

ILSVRC is on a subset of ImageNet containing more than 1 million images in

1000 classes

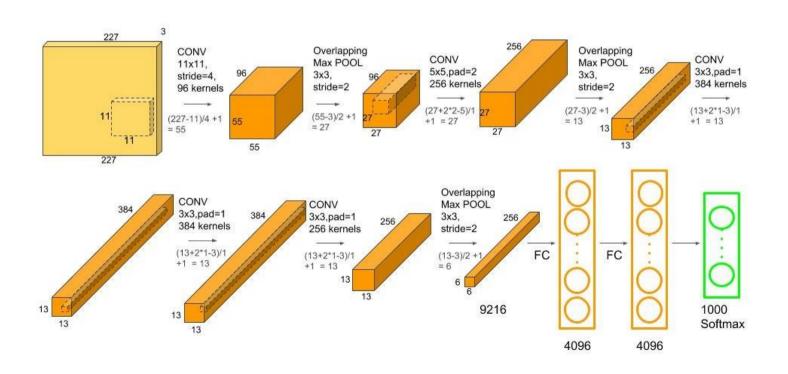

AlexNet

- Train on 2 GPUs
- GTX-580, 3GB memory
- Cross-GPU parallelization

- Local response normalization and Dropout
- Data augmentation and preprocessing
- 60 million parameters
- 17% top-5 error rate

AlexNet

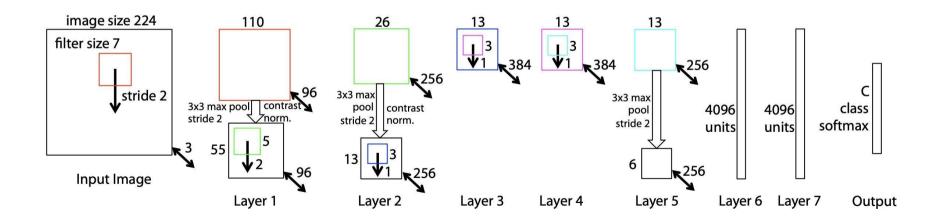

ZFNet

Alexnet but:

Conv1: change from (11 * 11 stride 4) to (7 * 7 stride 2)

Conv3, 4, 5: instead of 384, 384, 256 filters use 512, 1024, 512

VGG

- 3*3 Conv, stride 1, pad 1
- 2*2 max pool stride 2
- Stack of 3*3 filters has the
 Same receptive field as 7*7
- More non-linearities
- Fewer parameters
- 138M parameters
